

# Decision Tree

# Decision Tree

- **Decision tree is one of the most popular classification type of algorithm**
- **Classification is done by tree like structures that have different test criteria for a variable at each of the nodes**
- **New leaves are generated based on the results of the tests at the nodes**
- **Decision Tree is a supervised learning system in which classification rules are constructed from the decision tree**

# Decision Tree

**ID3, stands for “Inductive Dichotomizer”, this is a non-incremental algorithm, which means that it derives its classes from a fixed set of training data**

**Incremental algorithms can revise developed concepts if necessary, using a new sample, but the decision trees ID3 algorithm in contrast, is an inductive type**

**In inductive type algorithms specific classes once created, are expected to work for all future instances or data with the same dimensions**

**ID3 is a greedy algorithm, which constructs a decision tree in the top down recursive manner, and never checks back on its previous decisions**

# Concept Learning Systems

ID3 is an improved version of a Concept Learning System (CLS)

## CLS Algorithm:

### Step 1:

If  
All instances in training dataset,  $C$  are positive

then  
Create YES node and halt

If  
All instances in training dataset,  $C$  are negative

then  
create NO node and halt

Otherwise select a feature,  $F$  with values  $v_1, v_2, \dots, v_n$  and create a decision node.

### Step 2:

Partition the training instances in  $C$  into subset  $C_1, C_2, \dots, C_n$  according to the value of  $V$

### Step 3:

Apply the algorithm recursively to each of the sets  $C_i$

# Decision Trees

- **Decision trees represent attribute-based descriptions of concepts:**
  - We assume a universe of objects of interest (e.g. the set of all animals)
  - A “concept” is defined by the subset of objects which satisfy it (e.g. the concept of a “fox”, as defined by the set of all foxes)
  - Each object has a number of attributes, or properties (e.g. “colour”, “has\_fur”, “eats\_meat”, etc.)
  - The decision tree defines the concept in terms of the values of these attributes that an example must have
- **Often, decision trees define Boolean Functions: Input to the tree is an object described by a set of properties; output is “Yes/No”**

# Decision Trees

- Each internal node in the tree corresponds to a test of the value of one attribute, with branches to each of the possible values of that test.
- Each leaf node specifies the Boolean output of the tree if that point is reached.
- The aim is to learn a definition of the *goal predicate* for the problem at hand.
  - The goal predicate can be seen as a logical rule defining the concept – equivalent to the decision tree.

# Example – Restaurant Problem

- Should we wait for a table at a restaurant?

- Input Attributes:

- Alternate – Suitable alternative restaurant nearby?
- Bar – Is there one to wait in?
- Fri/Sat – Is it Friday or Saturday?
- Hungry – Are we?
- Patrons – How many (None, Some, Full)?
- Price – How pricey is this place?
- Raining – Is it?
- Reservation – Have we made one?
- Type – Of food (French, Italian, Burger, . . . ).
- WaitEstimate – How long, estimated by the host.

- Determine output attribute: *WillWait*.

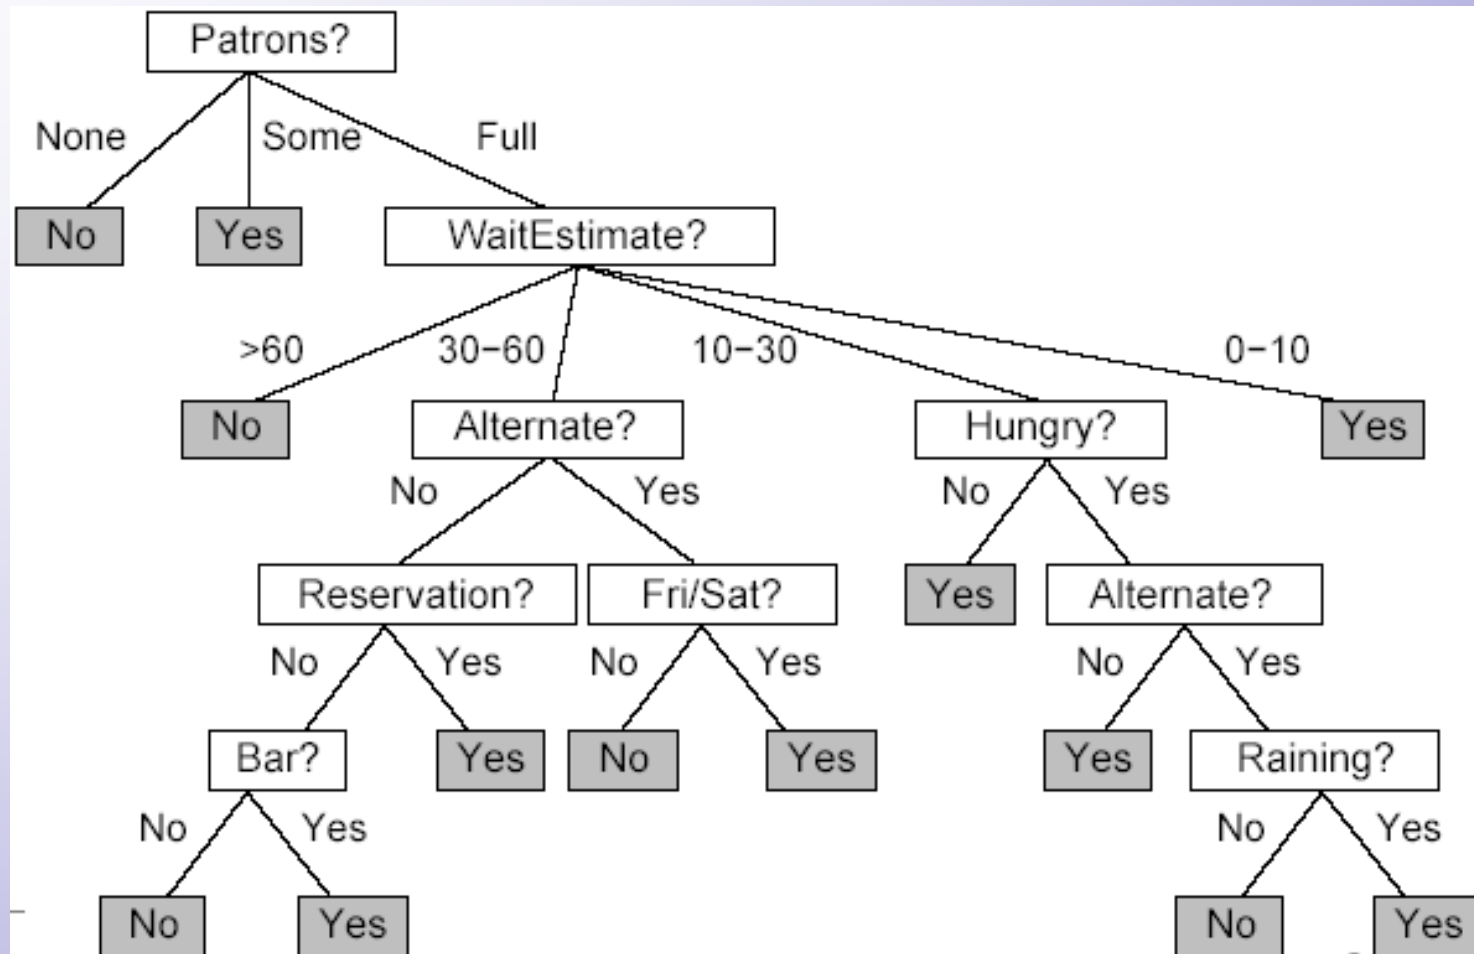

# Some Training Examples

| Example    | Attributes |            |            |            |            |              |             |            |             |            | Goal<br>WillWait? |
|------------|------------|------------|------------|------------|------------|--------------|-------------|------------|-------------|------------|-------------------|
|            | <i>Alt</i> | <i>Bar</i> | <i>Fri</i> | <i>Hun</i> | <i>Pat</i> | <i>Price</i> | <i>Rain</i> | <i>Res</i> | <i>Type</i> | <i>Est</i> |                   |
| <b>X1</b>  | Yes        | No         | No         | Yes        | Some       | \$\$\$       | No          | Yes        | French      | 0-10       | <b>Yes</b>        |

| <b>X11</b> | No         | No         | No         | No         | None       | \$           | No          | No         | Thai        | 0-10       | <b>No</b>         |
| <b>X12</b> | Yes        | Yes        | Yes        | Yes        | Full       | \$           | No          | No         | Burger      | 30-60      | <b>Yes</b>        |

- We need a collection of example objects (rows in a table), each with values for all the attributes and the values of the “output class”
- Positive (Yes) and Negative (No) examples are needed

# Possible Decision Tree

# How to Construct a Decision Tree

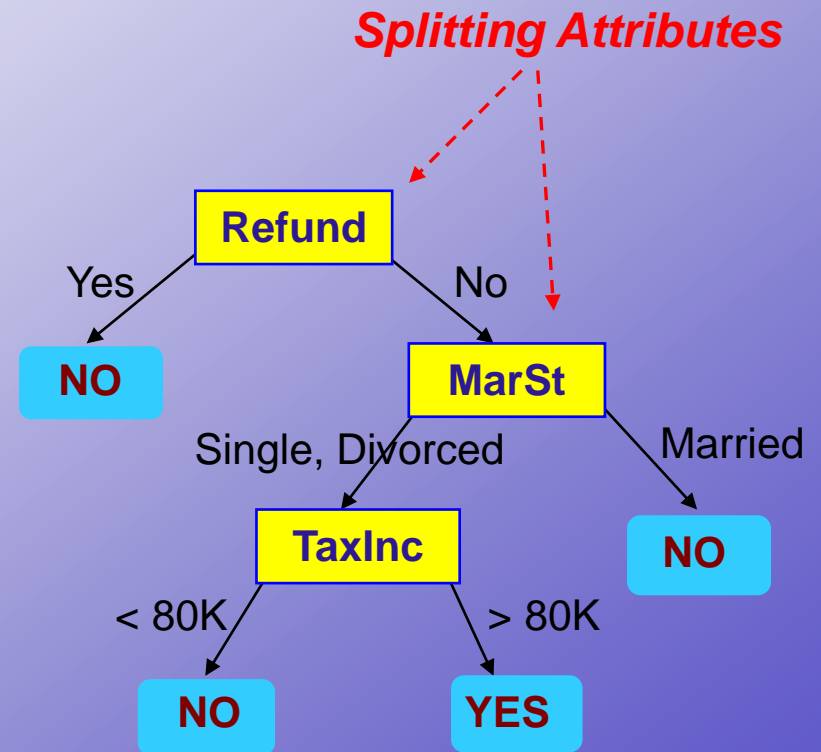

- **Given a table of positive & negative examples, each with an output class, how do we produce a decision tree for this training data set?**
- **Observe that each non-leaf node of the tree gives a test on one of the attributes in the dataset.**
- **Any example will satisfy only one of the options given.**
- **Therefore, the tree splits the training dataset between the branches of the tree according to attribute values.**
- **So, we start at the root node with all the training examples, and choose an attribute to split on.**
- **Each of the daughter nodes gives a subset of the training set.**
- **Then we can do exactly the same thing with each daughter node, until the examples remaining are all “Yes” or all “No”, or we run out of attributes.**

Test Set

# How to determine the Best Split

**Before Splitting: 10 records of class 0,  
10 records of class 1**

**Which test condition is the best?**

# How to determine the Best Split

- Greedy approach:
  - Nodes with **homogeneous** class distribution are preferred
- Need a measure of node impurity:

|       |
|-------|
| C0: 5 |
| C1: 5 |

Non-homogeneous,  
High degree of impurity

|       |
|-------|
| C0: 9 |
| C1: 1 |

Homogeneous,  
Low degree of impurity

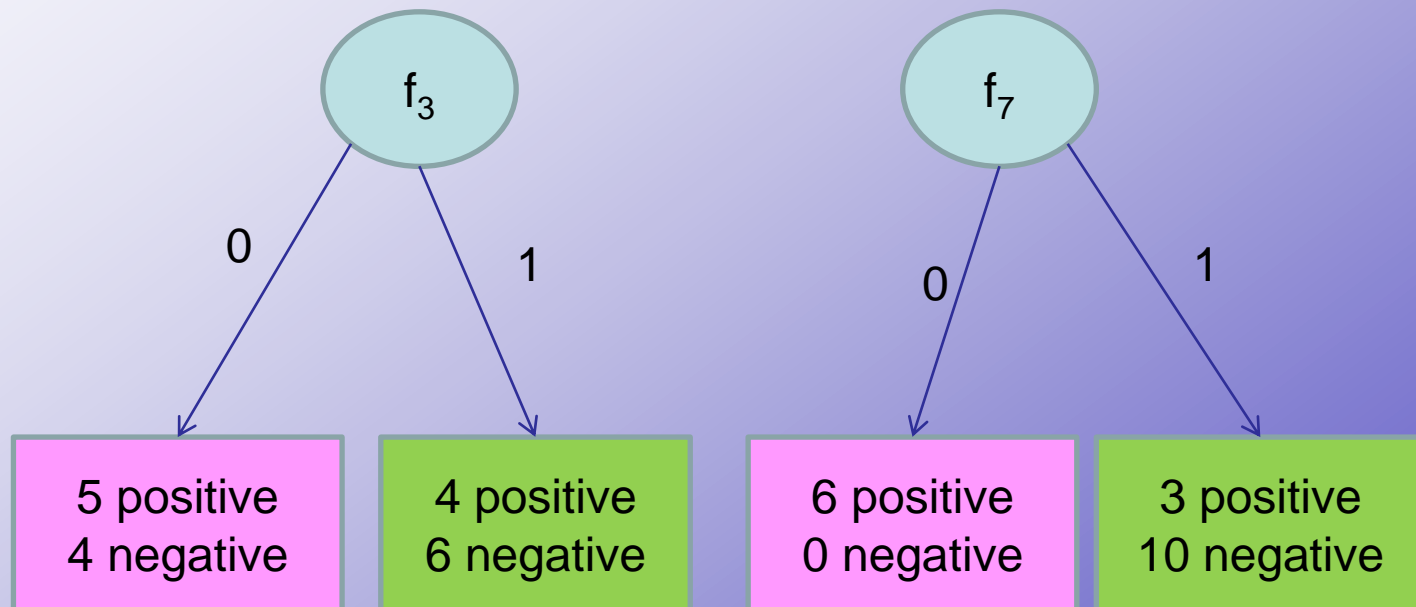

# Measures of Node Impurity

- Gini Index
- Entropy
- Misclassification error

# Let's Split

D: 9 positive  
10 negative

Selecting  $f_3$  doesn't help much as mixture is still with almost the same ratio compared with  $f_7$  which seems to be a good selection

# Entropy

$p$  := proportion of positive examples in data set

$$H = -p \log_2 p - (1-p) \log_2 (1-p)$$

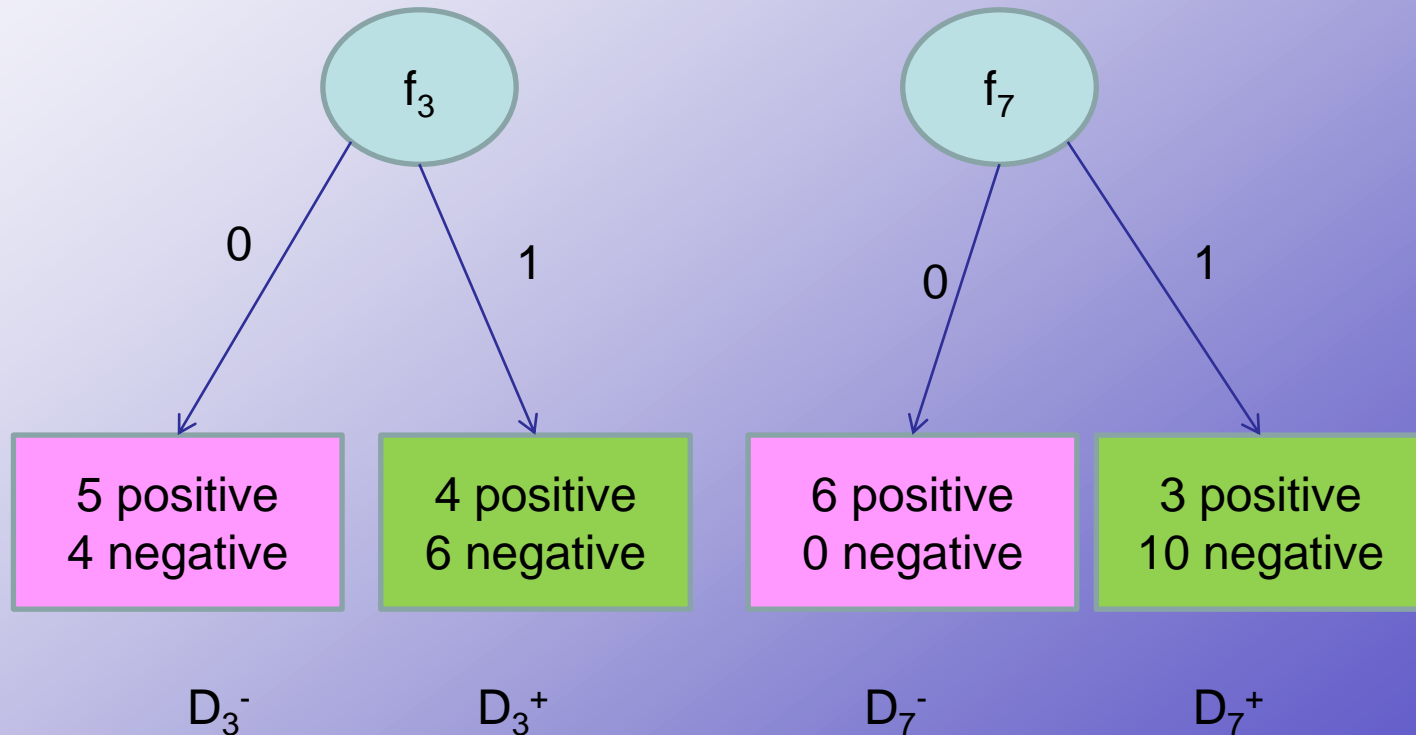

$$0 \log_2 0 = 0$$

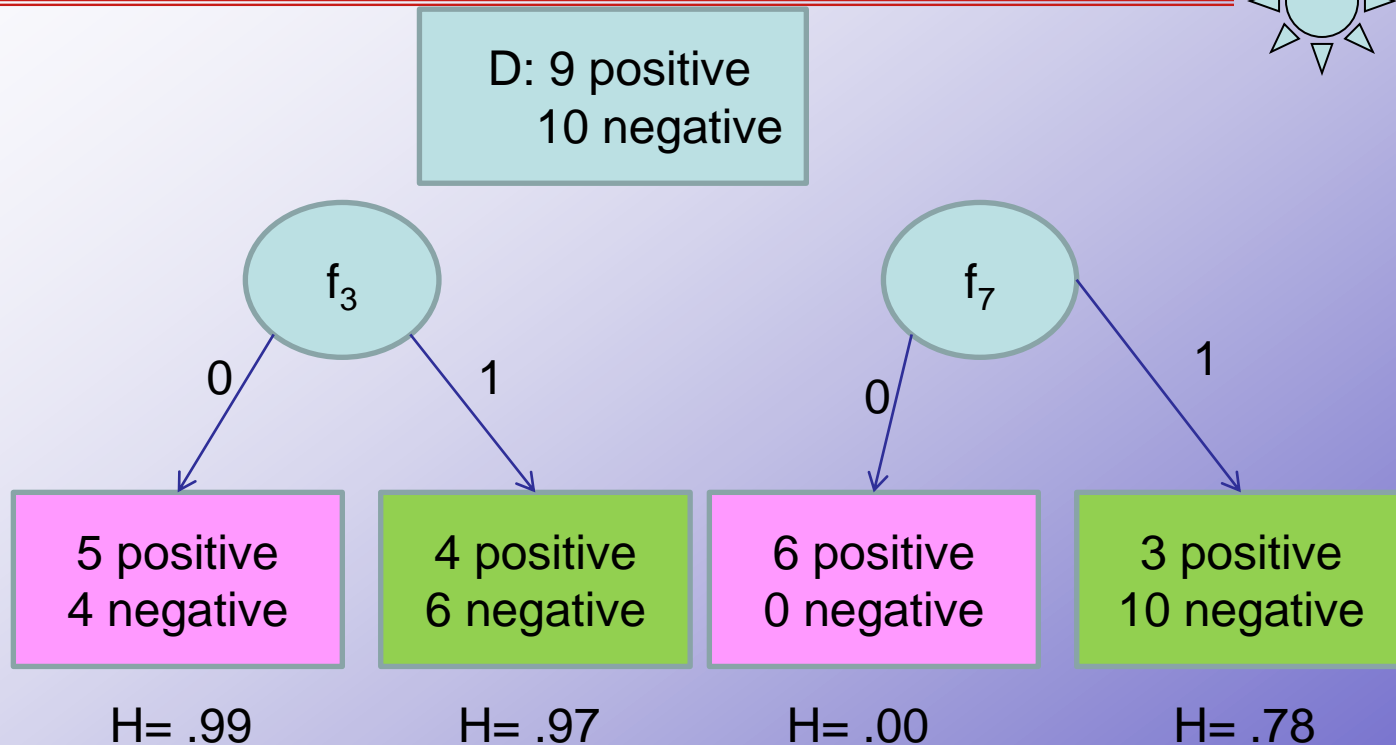

# Let's Split

D: 9 positive  
10 negative

# Let's Split

$$AE(j) = P_j H(D_j^+) + (1 - p_j) H(D_j^-)$$

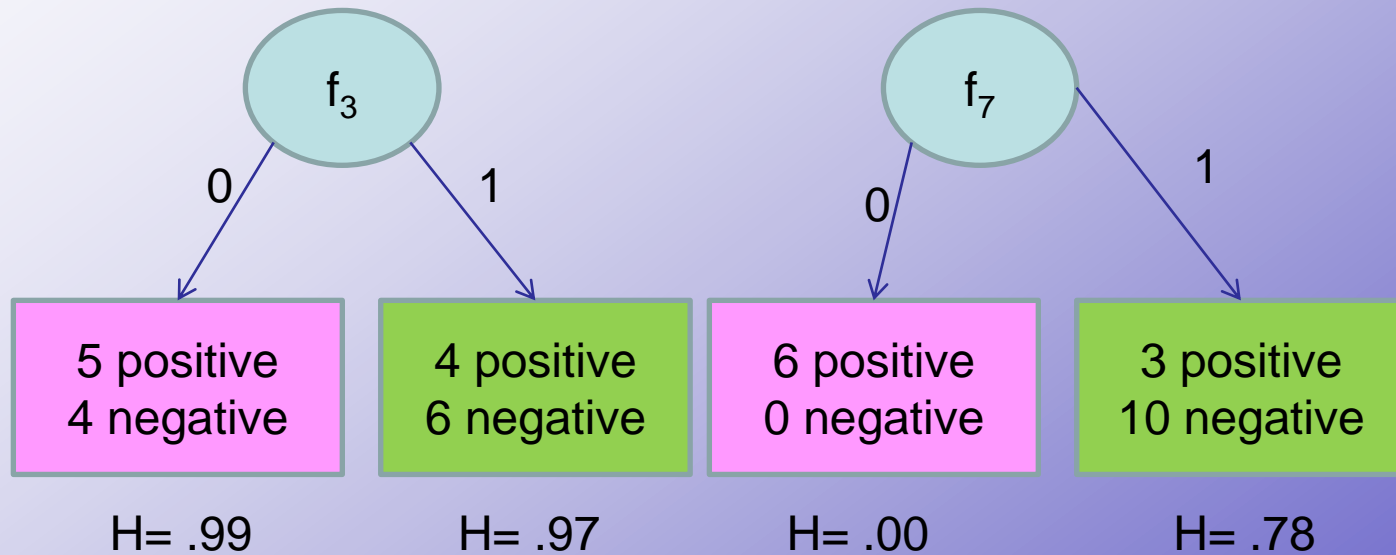

% of D with  $f_j=1$

subset of D with  $f_j=1$

# Let's Split

D: 9 positive  
10 negative

$$\begin{aligned} \text{AE} &= (9/19) * .99 + (10/19) * .97 \\ &= .98 \end{aligned}$$

$$\begin{aligned} \text{AE} &= (6/19) * .00 + (13/19) * .78 \\ &= .53 \end{aligned}$$

# Algorithm

---

**BuildTree(Data)**

**if all elements of Data have the same y value, then**

**MakeLeafNode(y)**

**else**

**feature := PickBestFeature(Data)**

**MakeInternalNode(feature,**

**BuildTree(SelectFalse(Data,Feature)),**

**BuildTree(SelectTrue(Data,Feature)))**

- Best feature minimizes average entropy of data in the children

# Stopping

---

- Stop recursion if data contains only multiple instances of the same  $x$  with different  $y$  values
  - ❖ Make leaf node with output equal to the  $y$  value that occurs in the majority of the cases in the data
- Consider stopping to avoid over-fitting when:
  - ❖ Entropy of a data set is below some threshold
  - ❖ Number of elements in a data set is below threshold
  - ❖ Best next split does not decrease average entropy

# Example

Entropy for each feature

- $AE_1 = .92$

- $AE_2 = .92$

- $AE_3 = .81$

- $AE_4 = 1$

The best feature for split is  $f_3$

| $f_1$ | $f_2$ | $f_3$ | $f_4$ | $y$ |
|-------|-------|-------|-------|-----|
| 0     | 1     | 1     | 0     | 0   |
| 1     | 0     | 1     | 1     | 1   |
| 1     | 1     | 1     | 0     | 1   |
| 0     | 0     | 1     | 1     | 1   |
| 1     | 0     | 0     | 1     | 0   |
| 0     | 1     | 1     | 1     | 0   |

# Simulation

# Simulation

| $f_1$ | $f_2$ | $f_3$ | $f_4$ | $y$ |
|-------|-------|-------|-------|-----|
| 0     | 1     | 1     | 0     | 0   |
| 1     | 0     | 1     | 1     | 1   |
| 1     | 1     | 1     | 0     | 1   |
| 0     | 0     | 1     | 1     | 1   |
| 0     | 1     | 1     | 1     | 0   |

- $AE_1 = .55$
- $AE_2 = .55$
- $AE_4 = .95$
- Arbitrarily decide to split on  $f_1$

# Simulation

# Simulation

# Simulation

# Simulation

# Pruning

---

- Best way to avoid over-fitting and not get tricked by short-term lack of progress

- Grow tree as far as possible

  - ❖ Leaves are uniform or contain a single X

- Prune the tree until it performs well on held-out data

- Amount of pruning is like epsilon in DNF algorithm

Pre pruning

Post Pruning

# ML

---

- Making useful predictions in (usually corporate) applications
- Decision trees very popular because :
  - ❖ Easy to implement
  - ❖ Efficient (even on huge data sets)
  - ❖ Easy for humans to understand resulting hypotheses
